

What the harness assumes

$c = \lceil C_{\text{config}} \cdot S \rceil$ workers, each turning a request round in exactly S

so capacity $= c/S = C_{\text{config}}$

What a worker actually pays

$\delta = 0.463$ ms,
unaccounted for in C_{config}

$C_{\text{model}} = c/(S + \delta) = C_{\text{config}} \cdot S/(S + \delta)$ — the same δ costs proportionally more when S is short
